Outline

1 Introduction
   - Helicopter Simulation
   - Time Spectral Method

2 Time Spectral Method
   - Time Spectral Method Formulation

3 Rotorcraft Simulation Results
   - Basic Forward Flight Calculations
   - Computational Cost
   - Lifting Forward Flight Calculations

4 Vorticity Confinement
   - Introduction
   - Formulation
   - Compressible Euler Calculations
   - Application to Rotorcraft Flows
INTRODUCTION
Helicopter simulation is very complex and computationally expensive:

- The flow is highly nonlinear.
- Interactions between the vortices with the blades and fuselage.
- There is a wide range of scales.
- Blades are highly elastic.
- Variety of blade motion:
  - Lead
  - Lag
  - Flapping
  - Collective pitch, cyclic pitch, yaw
Articulated Rotor

Forward Flight

A lot has been done over the past 3 decades.

- Potential flow calculations:
  - Caradonna & Isom (1972, 1976)
  - Caradonna & Philippe (1976)
  - Arieli, Taubert & Caughey (1986): the first three-dimensional, full potential flow based on Jameson & Caughey’s FLO22

- Euler and Reynolds averaged Navier–Stokes (RANS) calculations:
  - Agarwal & Deese (1987, 1988)
  - Srinivasan et al. (1991, 1992)
What is the Time Spectral Method?
Time Spectral Method

- Time integration method based on Fourier representation.
- Efficient and accurate method for periodic problems.
- No need to Fourier transform variables back and forth between time and frequency domains, everything is solved in the time domain.
- Algorithm is easily adapted to the current solvers.
  - Existing convergence acceleration techniques are applicable.
- The method is able to achieve spectral accuracy in theory.
What Has Been Done?

Fully nonlinear methods:

Time Spectral Method
The discrete Fourier transform of the flow variables $\mathbf{w}$ for a time period $T$ is

$$
\hat{\mathbf{w}}_k = \frac{1}{N} \sum_{n=0}^{N-1} \mathbf{w}^n e^{-i k \frac{2\pi}{T} n \Delta t},
$$

and its inverse transform:

$$
\mathbf{w}^n = \sum_{k=-\frac{N}{2}}^{\frac{N}{2}-1} \hat{\mathbf{w}}_k e^{i k \frac{2\pi}{T} n \Delta t}. 
$$

(1)
The spectral derivative of equation (1) with respect to time at the \( n \)-th time instance is given by

\[
Dw^n = \frac{2\pi}{T} \sum_{k=-N/2+1}^{N-1} ik\hat{w}_k e^{ik\frac{2\pi}{T}n\Delta t}.
\]

The right hand side can be written in terms of the flow variables \( w^n \) as follows:

\[
Dw^n = \sum_{j=0}^{N-1} d^n_j w^j
\]

where

\[
d^n_j = \begin{cases} 
\frac{2\pi}{T} \frac{1}{2} (-1)^{n-j} \cot \left\{ \frac{\pi(n-j)}{N} \right\} & : \ n \neq j \\
0 & : \ n = j
\end{cases}
\]
Let $n - j = -m$, one can rewrite the time derivative as

$$Dw^n = \sum_{m=-\frac{N}{2}+1}^{\frac{N}{2}-1} d_m w^{(n+m)}$$

where $d_m$ is given by

$$d_m = \begin{cases} 
\frac{2\pi}{T} \frac{1}{2} (-1)^{m+1} \cot \left\{ \frac{\pi m}{N} \right\} & : m \neq 0 \\
0 & : m = 0 
\end{cases}.$$
The original flow equations in semi-discrete form:

\[ \mathcal{V} \frac{d\mathbf{w}^n}{dt} + R(\mathbf{w}^n) = 0, \]

becomes

\[ \mathcal{V} D\mathbf{w}^n + R(\mathbf{w}^n) = 0. \tag{2} \]

These comprise a four dimensional coupled space–time set of nonlinear equations, which need to be solved simultaneously. For this purpose we introduce a pseudo time derivative term to equation (2), the equations can now be marched towards a periodic steady state using well known convergence acceleration techniques.

\[ \mathcal{V} \frac{d\mathbf{w}^n}{d\tau} + \mathcal{V} D\mathbf{w}^n + R(\mathbf{w}^n) = 0. \]
Flow Solver Methodology

1. Convergence Acceleration via
   - Modified 5-stage Runge–Kutta★
   - Local time stepping★
   - Multigrid★

2. Space Discretization:★
   - Jameson–Schmidt–Turkel (JST)
   - Symmetric Limited Positive (SLIP)
   - Convective Upwind and Split Pressure (CUSP)

3. Internal mesh generator via conformal mapping

ROTORCRAFT SIMULATION RESULTS
Hover Calculations were Presented at 46th AIAA Aerospace Sciences Meeting and Exhibit, Reno, NV

AIAA Paper 2008–403
Forward Flight Calculations
Experimental setup:

- Untapered, untwisted two-bladed rotor
- NACA 0012 section
- Aspect ratio of 7
- Diameter of the rotor is 7 ft
- Chord is 6 in
Nonlifting Rotor in Forward Flight

- Flow Condition:

\[
\begin{align*}
\theta_c &= 0^\circ \\
M_{\text{tip}} &= 0.8 \\
\mu &= 0.2 \\
Re &= 2.89 \times 10^6
\end{align*}
\]

- Twelve time instances were used, \( N = 12 \)
Mesh

- Euler: $128 \times 48 \times 32$ cells per blade, 16 cells on the blade.
- RANS: $192 \times 64 \times 48$ cells per blade, 32 cells on the blade.

Nawee Butsuntorn & Antony Jameson

Time Spectral Method for Rotorcraft Flow with VC
Computational Cost

- 300 multigrid cycles for Euler calculations.
  - Residual reduced by four orders of magnitude.
- 500 multigrid cycles for RANS calculations.
  - 5 hours on four dual-core processors (clock speed is 3.0 GHz).
  - Residual reduced by three orders of magnitude.
Comparison with Backward Difference Formula (BDF)

\[ \nu \left\{ \frac{3}{2\Delta t} w^{n+1} - \frac{4}{2\Delta t} w^n + \frac{1}{2\Delta t} w^{n-1} \right\} + R(w^{n+1}) = 0. \]

- Periodicity is established, not enforced.
- Usually requires at least 4 cycles (for pitching airfoil/wing).

For the same RANS calculations, the BDF would need:

- 180 time steps per revolution
- 40 multigrid cycles per time step
- 6 cycles to convergence

⇒ 43200 steps

Time Spectral method used 500 multigrid cycles with 12 time instances

In terms of the number of multigrid cycles required ...

Time Spectral method is 87 times faster

In terms of CPU hours ...

Time Spectral method is still 7.2 times faster
Time-Lagged Periodic Boundary Condition

- First proposed by Ekici & Hall (2008)
- One blade is required for forward flight simulations
- Further saving of $N_b$ times

where $N_b$ is the number of blades per rotor

$$w(r, \psi, z, t) = w\left(r, \psi - \frac{2\pi}{N}, z, t - \frac{T}{N}\right)$$

Time-Lagged Periodic Boundary Condition
Euler Calculations

- Collective pitch, $\theta_c = 0^\circ$
- Tip Mach number, $M_{\text{tip}} = 0.7634$
- Advance ratio, $\mu = 0.25$
- $128 \times 48 \times 32$ mesh cells
Euler Calculations

(a) $\psi = 30^\circ$
(b) $\psi = 60^\circ$
(c) $\psi = 90^\circ$
(d) $\psi = 120^\circ$
(e) $\psi = 150^\circ$
(f) $\psi = 180^\circ$

experiment, — JST scheme, – – CUSP scheme
Lifting Rotor in Forward Flight
Caradonna & Tung Experiment (1981)
Test Case

- Caradonna & Tung rotor
- Collective pitch, $\theta_c = 8^\circ$
- Tip Mach number, $M_{\text{tip}} = 0.7$
- Advance ratio, $\mu = 0.2857$
Numerical Data Provided by C. B. Allen

- Over 2 million mesh points around the two blades and hub (not including the other blocks that cover the far-fields)
- BDF time stepping scheme
- 180 steps per revolution
- 6 revolutions
- Periodicity is established after the second revolution
- JST dissipation scheme
- 70 3-level V-cycle multigrid cycles per time step

Load variation on each blade around the azimuth

\[ C_L = \frac{F_y}{\frac{1}{2} \rho (\Omega R)^2 c R} \]

where

- \( F_y \) = force in the \( y \) direction
- \( \Omega \) = angular velocity
- \( c \) = chord
- \( R \) = rotor radius
- \( \rho \) = density

Vorticity Confinement
What is Vorticity Confinement?

- John Steinhoff first suggested the idea in 1994.
- A forcing term added to the momentum equations (inviscid, incompressible), “so that as the vorticity diffuses away from the centroids of vortical regions, it is transported back”.
- Vorticity is added in the direction normal to both \( \vec{\omega} \) and the gradient \( |\vec{\omega}| \).
- Unfortunately momentum is not conserved.
Steinhoff & Underhill (1994); Steinhoff (1994):

$$\frac{\partial \mathbf{u}}{\partial t} + (\mathbf{u} \cdot \nabla) \mathbf{u} = \frac{1}{\rho} \nabla p + \mu \nabla^2 \mathbf{u} - \epsilon \mathbf{s}$$

where the simplest form of $\mathbf{s}$ is

$$\mathbf{s} = \frac{\nabla |\vec{\omega}|}{|\nabla |\vec{\omega}||} \times \vec{\omega}$$
Hu & Grossman (2001); Hu et al. (2001) and Dadone et al. (2001) introduced a body force per unit mass term to the total energy equation:

$$\int_{\Omega} \frac{\partial \mathbf{w}}{\partial t} \, d\mathbf{v} + \oint_{\partial \Omega} \mathbf{f}_j \cdot \mathbf{n} \, dS = - \int_{\Omega} \mathbf{\varepsilon} \mathbf{s} \, d\mathbf{v}$$

where $\mathbf{s}$ is now:

$$\mathbf{s} = \begin{bmatrix} 0 \\ \rho(\hat{\mathbf{n}} \times \mathbf{\omega}) \cdot \mathbf{i} \\ \rho(\hat{\mathbf{n}} \times \mathbf{\omega}) \cdot \mathbf{j} \\ \rho(\hat{\mathbf{n}} \times \mathbf{\omega}) \cdot \mathbf{k} \\ \rho(\hat{\mathbf{n}} \times \mathbf{\omega}) \cdot \mathbf{u} \end{bmatrix}$$

and

$$\hat{\mathbf{n}} = \frac{\nabla|\mathbf{\omega}|}{|\nabla|\mathbf{\omega}|}.$$
Making $\epsilon$ Dimensionless and Dynamic

- Fedkiw *et al.* (2001) for incompressible Euler equations on structured meshes
  \[ \epsilon_h \propto \epsilon h \]

- Löhner & Yang (2002); Löhner *et al.* (2002) for incompressible RANS calculations on unstructured meshes
  \[ \epsilon_v \propto \begin{cases} \epsilon |u| \\ \epsilon h |\bar{\omega}| \\ \epsilon h^2 |\nabla|\bar{\omega}| \end{cases} \]
Robinson (2004)

- Chose to scale $\epsilon$ is with $|u|$
- Factor out $|\vec{\omega}|$ from $s \left( = \frac{\nabla |\vec{\omega}|}{|\nabla |\vec{\omega}||} \times \vec{\omega} \right)$
- $\Rightarrow |u| \cdot |\vec{\omega}|$
- $|u \cdot \vec{\omega}| \equiv$ helicity

$$s = \rho |u \cdot \vec{\omega}| \left\{ \frac{\nabla |\vec{\omega}|}{|\nabla |\vec{\omega}||} \times \frac{\vec{\omega}}{|\vec{\omega}|} \right\}$$
New Formulation

Combine
1. Helicity form
2. Body force per unit mass term in energy equation
3. Scaling based on cell size

\[ s = |\mathbf{u} \cdot \mathbf{\omega}| \left[ 1 + \log_{10} \left( 1 + \frac{\mathcal{V}}{\mathcal{V}_{\text{averaged}}} \right)^{1/3} \right] \]

where
\[ \hat{n} = \frac{\nabla|\mathbf{\omega}|}{|\nabla|\mathbf{\omega}|}. \]
NACA 0012 Wing

Test Case:
- Euler calculation
- Untwisted, untapered wing with NACA 0012 cross section
- Aspect ratio of 3

\[ \alpha = 5^\circ \]
\[ M_\infty = 0.8 \]

(e) $\psi = 150^\circ$
(f) $\psi = 180^\circ$

× Allen, — computed result
- $x = 2$ and $x = 5$
- 1st time instance, i.e. $\psi = 90^\circ$
Time Spectral method has proved to be an efficient method for periodic problems, providing that the number of time instances are enough to capture the smallest frequency.

Vorticity confinement works well for fixed-wing calculations.

The vortical structure in lifting rotor in forward flight could be controlled such that the effect of blade–vortex interaction became more apparent as $\epsilon$ increased.

... but further studies are needed for rotorcraft application, at least with the current mesh geometry.

Perhaps H-mesh would be better suited, or one can resort to overset or unstructured meshes.
Conclusion

- Hover calculation takes much longer than forward flight calculation (surprisingly).
- Time Spectral method is approximately 10 times faster than the traditional backward difference formula (depending on the number of time instances required).
- RANS calculations for nonlifting rotor in forward flight took only 5 hours on four dual-core processors with 500 multigrid cycles.
- Using the time-lagged boundary condition, computational expense can be reduced by $N_b$ times.
- New formulation for vorticity confinement has no effect on the distribution of $C_p$ for fixed-wing transonic flow calculations.
- The maximum error for $c_l$ and $c_d$ for was only 1.3%.
The authors would like to thank Professor Chris Allen for his data for our comparison purpose.
